

Backend change to apply: real “Profile strength” data

This wasn't done through git (this sandbox's backend/ folder isn't a git repo here), so it needs to be applied by hand to your working copy of backend/main.py on the real repo (Sdmne/LBP2).

What it does

Adds a profileCompleteness (0-100 integer) field to the response of GET /api/auth/me, so the mobile app (and eventually the website) can show a real “Profile strength” bar instead of a fake one.

It's not new logic - catalog_profile_completeness_sql() already computes this same 7-factor score in SQL for catalog ranking (profileType, avatarUrl, dateOfBirth, country, city, lookingFor, plus about-or-bio). This just ports the same 7 factors to Python and exposes the result on /api/auth/me, since a client already calling that endpoint shouldn't need a second round trip just to get a completeness percentage.

How to apply

Two options, whichever's easier on your end:

1. **Apply the attached patch** (profile_completeness.patch) with:

```
git apply profile_completeness.patch
```

from the repo root (adjust the path if your checkout doesn't have backend/ at the same level). If it doesn't apply cleanly because your main.py has diverged, use option 2.

2. **Apply by hand** - two small, self-contained edits:

- a. Add this new function right after profile_is_verified() (search for that function name to find the spot):

```
def profile_completeness_percent(profile: dict[str, Any] | None)
-> int:
    """Same 7-factor completeness
    catalog_profile_completeness_sql() computes
    in SQL for ranking
    (profileType/avatarUrl/dateOfBirth/country/city/
    lookingFor, plus about-or-bio), done in Python so
    /api/auth/me can hand
    it to the mobile/web "Profile strength" bar without a second
    SQL round
    trip - kept in sync with that function's own field list on
    purpose, so
    if one changes the other should too."""
    data = profile_data(profile)

    def filled(key: str) -> bool:
        value = data.get(key)
        if value is None:
            return False
        text = str(value).strip()
        return text not in ("", "null", "[]", "{}")
```

```
        factors = [filled(f) for f in ("profileType", "avatarUrl",
"dateOfBirth", "country", "city", "lookingFor")]
        factors.append(filled("about") or filled("bio"))
        return round(100 * sum(1 for f in factors if f) /
len(factors))
```

- b. In `auth_me()` (the GET `/api/auth/me` handler), add one line right after the existing `isPremium` line:

```
        result["profileCompleteness"] =
profile_completeness_percent(profile)
```

After deploying

No mobile/client change needed - the mobile app already reads this field (shipped this session) and just shows nothing extra until it's present. Once this is live on `test.letsbeparents.com`, the "Profile strength" bar on the Profile tab will show the real percentage.
